## Ages 17-19 – CAS your girl friend

A young man is saying good-bye to his girl friend at the platform just outside the last door at the back of a train. When the train signals departure he is kissing her so warmly that he does not hear the signal. We assume that the train has a constant acceleration of  $a = 0.40 \text{ m/s}^2$  and that he starts running at a constant speed 6.0 s after the train began accelerating. Can he catch the train?

All distances are in meters and time in seconds.

The train starts at t = 0 at the position y = 0.

The young man runs at the constant speed v m/s.

The position of the train door at time *t* is given by:  $y = y_1 = \frac{1}{2}at^2 = 0.20 \cdot t^2$ .

The position of the young man at time *t* is given by:  $y = y^2 = v \cdot (t - 6)$ .

We will now analyse this situation in three ways.

## 1. CAS the train 1 (using no calculus)

The graphs below show the distances as a function of time if the man runs at v = 6.0 m/s :

We see that in this case he has 2 opportunities to catch the train. If he runs too slowly, he will not be able to catch the train. The minimum speed  $v_{min}$  can be found by using the fact that in this case the equation y1 = y2 has one and only one solution for *t*. First solve the equation y1 = y2 with any speed *v* to find the two solutions for *t*. Then find *v* such that the two *t*-values are equal.

Thus the minimum speed in order to catch the train is  $v_{\min} = 4.8$  m/s (the solution v = 0 makes no sense). Again, we solve the equation  $y_1 = y_2$  for *t*, this time with v = 4.8.

■ solve[.2·t <sup>2</sup> = v·(t - 6), t]
$t = 2.5 \cdot 10 \cdot 10 - 4.8 + 2.5 \cdot 0$ or $t = 2.5 \cdot 0 - 10 \cdot 10 = 10 \cdot 10 \cdot 10 \cdot 10 \cdot 10 \cdot 10 \cdot$
<pre>solve(2.5.10.10 - 4.8 + 2.5.0 = 2.5.0 - 2. v = 4.8 or v =</pre>
<u>u=2.5*u-2.5*J(u)*J(u-4.8),u)</u>

We can now conclude that the minimum running speed required for the man to catch the train is 4.8 m/s. At that speed he will catch the train 12 seconds after the train started, after he has been running for 6 seconds and covered a distance of 28.8 m. We can show this in two ways:

He runs for 6 seconds:  $4.8 \text{ m/s} \cdot 6 \text{ s} = 28.8 \text{ m}$ The trains travels for 12 seconds:  $0.2 \text{ m/s}^2 \cdot (12 \text{ s})^2 = 28.8 \text{ m}$ .

If the man runs faster than 4.8 m/s, he will have two opportunities to catch the train.

## 2. CAS the train 2 (using calculus)

The young man is running at  $v = v_{\min}$  and the train has the same speed when he catches it.

Position of train door at time *t*:  $y = \frac{1}{2}at^2 = 0.20 \cdot t^2$ . Speed of train at time *t*:  $v = y'(t) = 0.40 \cdot t$ .

The speed of the young man can be written as:  $v = \frac{0.20 \cdot t_1^2}{t_1 - 6}$ , where  $t_1$  is the time when he catches the

train.

Once again we find that he catches the train  $t_1 = 12$  seconds after it started.

## 3. CAS the train 3 (using calculus)

Below we find the equation of the tangent line at the time  $t_1$  as the Taylor polynomial of order 1. Then solve for  $t_1$  requiring that y = 0 when t = 6:

(F17770) F27 ▼ ← Alget	ora Calc Other Pr	rs ∽gmIO Clean Up
,	· · ·	
∎taylorl.:	2·t <sup>∠</sup> ,t,1,t1J	1.(+ - + 1) + - 2.+12
∎solueĺ.4	.+	.t1 <sup>2</sup> =0.t1] t=6
- 50100(11		t1 = 12. or $t1 = 0$
<u>*t1*(t</u> Main	<u>-t1)+.2*t1^</u>	2=0,t1) t=6  FUNC 2/30

Once again we find that he catches the train  $t_1 = 12$  seconds after it started.

<u>Remark</u>: The model is not fully realistic. You might for instance introduce an acceleration period for the young man before he reaches the constant speed.
