

Consider the diagram shown on page 1.3. Use the coordinates of points  $p$  and  $q$  to determine the slope of  $\overrightarrow{pq}$ .

Imagine that you start moving point  $q$  towards point  $p$ . What do you think will happen to the slope of  $\overrightarrow{pq}$ ?

What will happen to the slope of  $\overrightarrow{pq}$  when  $p$  and  $q$  become the same point? What shall we call  $\overrightarrow{pq}$  when this happens?

### Investigating the slope of a tangent line graphically

Advance to page 1.4. You will see the screen at right showing the graph of the function  $f1(x) = x^2$  along with secant  $\overrightarrow{pq}$ . The slope,  $m$ , of  $\overrightarrow{pq}$  is also displayed on the screen.

Drag point  $q$  slowly towards point  $p$  and observe the effect on the slope. As you do this, periodically press  $(\text{ctrl}) + (\cdot)$ . This will capture the coordinates of point  $q$  into a spreadsheet, placing the  $x$ -values in Column A and the  $y$ -values in Column B. Make sure that you do this enough times that there are about 10 points contained in the spreadsheet by the time point  $q$  reaches point  $p$ .

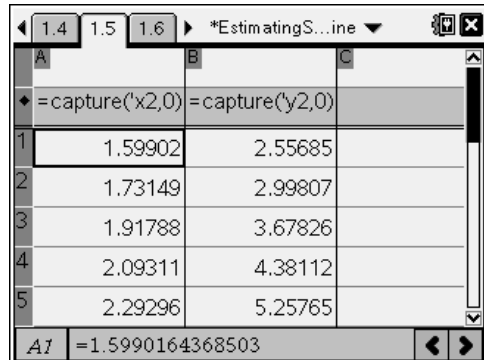

- As you moved point  $q$  towards point  $p$ , what value did the slope,  $m$ , approach?
- In the introduction to this activity, you used the formula for slope,  $m = \frac{y_2 - y_1}{x_2 - x_1}$ , to find the slope of the secant for  $p(1, 1)$  and  $q(2.5, 6.1)$ . Why is it not possible to use this formula when points  $p$  and  $q$  coincide?
- The slope of the tangent line is often referred to as the *instantaneous rate of change*. Explain what is meant by this.

## Estimating Slope of a Tangent Line

Advance to page 1.5. You will see the coordinates of point  $q$  that were recorded in a spreadsheet each time you pressed  $\text{(ctrl)} + \text{(.)}$ . Recall that point  $p$  is locked in as  $(1, 1)$ .

In cell C1, you will enter a formula to calculate the slope of  $\overline{pq}$  for your first captured point. You should use *cell references* rather than typing the actual numerical values found in A1 and B1.

	A	B	C
	=capture('x2,0)	=capture('y2,0)	
1	1.59902	2.55685	
2	1.73149	2.99807	
3	1.91788	3.67826	
4	2.09311	4.38112	
5	2.29296	5.25765	

Use **Fill Down** to copy this formula to all data values.

- How do the values contained in Column C compare with the values of the slope you observed in the graph screen?
- What would happen if a captured point had  $x$ - and  $y$ -coordinates **exactly** equal to 1?
- How can you estimate the value of the slope of a tangent line at a specific point using the slope formula?
