

Unit 3: Conditions, if and while

Skill Builder 3: Press a key

In this lesson you will use a function that looks for a *keypress* to terminate a loop. This feature is unique to the TI-Nspire so you will need to import one (or more) special modules.

Objectives:

- Use **get_key()** to end a loop
- Examine powers of 2 and powers of 1/2.
- Use **sleep(n)** to pause code execution for n seconds

Now that you've experienced the **while** loop, let's visit a special and powerful feature of the TI-Nspire Python system: **get_key()**. We will write a program that will display powers of 2 (2, 4, 8, 16, 32, 64, ...) continuously and will end only when the **esc** key is pressed.

1. Begin a new Python 'blank program' and name it '**powers_of_2**'.
2. Use **menu > More Modules > TI System** to get the statement

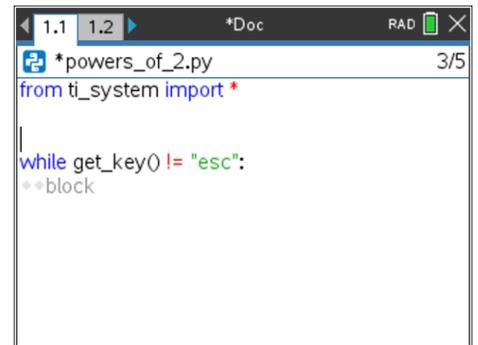

from ti_system import *

located at the top of the list.

On the same **menu**, select the special statement:

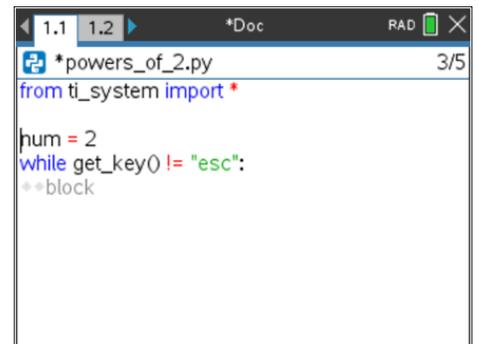

while get_key() != "esc":
block

3. Now introduce a variable **num = 2** just *before* the **while** statement.

```
*powers_of_2.py 3/5
from ti_system import *

while get_key() != "esc":
  **block
```

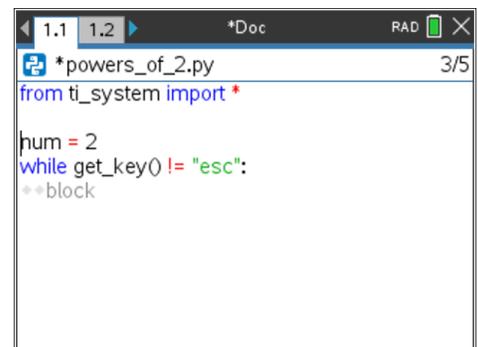

```
*powers_of_2.py 3/5
from ti_system import *

num = 2
while get_key() != "esc":
  **block
```

4. In the loop block, **print** the number and then make an **assignment statement** that will multiply it by 2. Be sure your statements are indented.

Try it yourself before checking the code in the next step...

```
*powers_of_2.py 3/5
from ti_system import *

num = 2
while get_key() != "esc":
  print(num)
  num = num * 2
  **block
```

5. Here you go...

```
while get_key() != "esc":
    print(num)
    num = num * 2
```

Run the program and press **esc** to stop it.

```
*powers_of_2.py 6/6
from ti_system import *

num = 2
while get_key() != "esc":
    print(num)
    num = num * 2
```

6. The numbers grow really fast!

Two interesting features of Python:

It's *really* fast and

there's *no upper limit* to the integers.

However, you *are* limited by the capacity of the computer's memory.

Your next task is to slow things down so that you can read the numbers.

```
Python Shell 240/240
19342813113834066795298816
38685626227668133590597632
77371252455336267181195264
154742504910672534362390528
309485009821345068724781056
618970019642690137449562112
1237940039285380274899124224

9903520314283042199192993792
>>>
```

7. You need a function called **sleep()** that is found in the Python **time** module.

At the top of your program add the statement

```
from time import sleep
```

located on the top of **menu > More Modules > Time**.

```
*powers_of_2.py 3/7
from ti_system import *
from time import sleep

num = 2
while get_key() != "esc":
    print(num)
    num = num * 2
```

8. Below the statement **num = num * 2** add the statement

```
sleep(1)
```

inside the **while** block (indented like the other two statements above it).

Run the program again. This time, after each number is displayed, the computer sleeps (waits) for one second before proceeding to the next step in the loop. Change the sleep number to speed things up a bit.

Again, press **esc** to end the program. Try other **sleep()** values to vary the speed of the display.

At the end of the program, print "Done".

```
*powers_of_2.py 8/8
from ti_system import *
from time import sleep

num = 2
while get_key() != "esc":
    print(num)
    num = num * 2
    sleep(1)
```

UNIT 3: SKILL BUILDER 3

STUDENT ACTIVITY

9. Change each **2** in the program to **0.5**.

What happens?

Try other numbers.

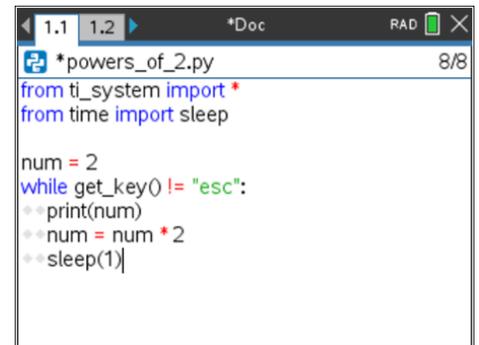

When do the numbers grow and when do they shrink?

How about negative numbers?

Would it make sense to try 0 or 1 instead of 2?

Now try this: Change **num = num * 2** to **num *= 2**

This shortcut operation does the same thing and works for many other mathematical operators.

```
*powers_of_2.py 8/8
from ti_system import *
from time import sleep

num = 2
while get_key() != "esc":
    print(num)
    num = num * 2
    sleep(1)
```
